Hintergrund

“Latency from a general point of view is a time delay between the cause and the effect of some physical change in the system being observed” [1]. Latency in video games impairs the performance of the player and game experience. The performance in fast-paced games like Counter-Strike: Global Offensive (CS:GO), which require precision and have tight deadlines, is dependend on the latency [2, 3]. There are three main latency compensation techniques to improve game experience and performance [4].

- Delayed input techniques try to add delay to local actions to allow simultaneous execution by all clients [4, 5].
- Time-offsetting techniques enable a rollback to the previous state of the game [4, 5].
- Predictive techniques estimate the occurring events in the game from the locally available state [4, 5].

The goal of this work is to build a predictive technique for CS:GO using artificial neural networks (ANN). ANNs have been successfully used in computer vision tasks, such as pattern recognition in images [8], to predict avatar movement in VR [7] or reduce perceived input latency on touch devices [4]. However, one problem of ANNs is their long runtime due to internal complexity [9]. If used for latency compensation in video games, the ANNs inference needs to be fast and lightweight. If inference takes too long an ANN based latency compensation technique ultimately leads to an

increase in overall latency.

This work aims to build and evaluate a predictive system to decrease perceived latency for CS:GO.

Zielsetzung der Arbeit

Firstly a suitable way to collect data from CS:GO needs to be implemented. There are two possible ways to collect data: (1) Directly log user input and game screen while live-playing and (2) use openly available CS:GO replays. Both approaches need to be evaluated and analyzed regarding their feasibility for this work's aim.

After collecting a suitable data set from either one of the above options the ANN needs to be developed. The ANN's prediction is based on the previously gathered data and ultimately should be able to infer the user's next inputs.

After training the ANN, it is evaluated in various scenarios. The goal is to determine if the developed predictive system is suitable for latency compensation in CS:GO.

Konkrete Aufgaben

- Literature research
- Create a suitable dataframe for ANN training
- Train the latency compensation model
- Evaluate the developed model
- Write the thesis

Erwartete Vorkenntnisse

- Tensorflow, Pytorch or Keras
- Programming in C++/Python and Unity
- Data analysis
